

# The SLP System: An Implementation of Super Logic Programs

Stefan Brass

Technical University of Clausthal, Germany

In part joint work with:

Jürgen Dix, Teodor C. Przymusiński

# Super Logic Programs (1)

- Arbitrarily nested propositional connectives.
  - ◇ Includes disjunctive logic programs and
  - ◇ integrity constraints (rules with empty head).
- Rule form not required: Clear separation between default negation and logical/classical negation.
- Variables.
  - ◇ Allowedness: Every variable must appear at least once in negated context outside default negation (i.e. a positive body literal).

## Super Logic Programs (2)

- Default negation can be used only in negated context (i.e. in the body).
  - ◇ The meaning of **not** is defined by a nonmonotonic semantics, and not by rules of the program.
- The static semantics permits  $\wedge$  and  $\vee$  inside **not**.
  - ◇ **not**  $(\varphi_1 \vee \varphi_2)$  is equivalent to **not**  $\varphi_1 \wedge$  **not**  $\varphi_2$ .
  - ◇ This does not hold for conjunction:  
**not** means falsity in all minimal models.

Probably no real expressiveness extension: Define new predicate.

# SLP Interpreter (1)

## Negation Semantics Currently Supported:

- Static Semantics: Query evaluation (disj. answers).
- Stable Models: Only model computation.

## Future Plans (Easy Extensions):

- Query evaluation (cred./skept.) for stable models
- D-WFS (Brass/Dix)
- More efficient minimal model computation for programs without default negation.

## SLP Interpreter (2)

- Written in C++, currently 21.000 lines of code
- Source code available under GNU public license
- <http://purl.oclc.org/NET/slp/>  
<http://www.informatik.uni-giessen.de/staff/brass/slp/>
- Web interface, local installation not necessary.  
Runs as CGI-Program. In development: Own HTTP server.
- Alternative: Classical console interface.

# Basic Steps

- Transformation into clauses (rules and cond. facts).
- Computation of implied **conditional facts** (hyperresolution, does grounding).
- Evaluation of **not** in obvious cases: **residual prog.**
- **For static semantics**: Iterative computation of static interpretations for remaining default negations, evaluation of conditional disjunctive answers.
- **For stable models**: Model computation of a disjunctive version of Clark's completion.

# Overview

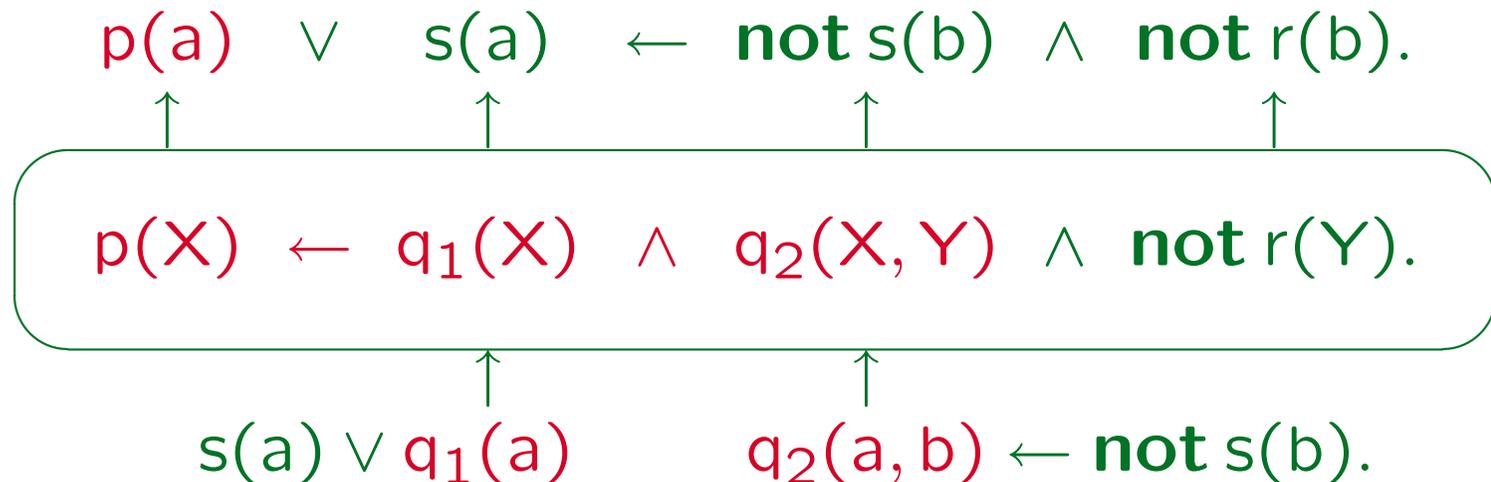

1. Computation of Residual Program
2. Static Semantics
3. Minimal Model Computation
4. Query Evaluation
5. Stable Models

# Conditional Facts

- Rule without positive body literals, i.e. of the form
$$p(a, b) \vee q(c) \leftarrow \mathbf{not} r(d) \wedge \mathbf{not} s(e, f).$$
- Because of the allowedness restriction, variables cannot appear.
- For the static semantics, conditional facts can contain negations of the form  $\mathbf{not} (q(a) \wedge q(b))$ .

# Hyperresolution

- Generalization of  $T_P$ -operator to conditional facts.
- Disjunctive context or condition of a fact matched with a body literal is appended to the derived fact:

# Hyperresolution Fixpoint

- **Theorem:** Let  $F$  be the least fixpoint of the hyperresolution operator for a program  $P$ . A Herbrand interpretation  $I$  is a minimal model of  $F$  iff it is a minimal model of the ground instantiation  $P^*$  of  $P$ .
- **Minimal model:** Minimal given a fixed interpretation for the default negation literals.
- **Theorem:** If a semantics permits unfolding and elimination of tautologies,  $F$  is equivalent to  $P^*$ .

# Duplicate Elimination (1)

- Duplicate conditional facts must be detected in order to guarantee termination.
- Also non-minimal conditional facts are eliminated immediately in SLP.
- E.g.  $p(a) \vee p(b) \leftarrow \text{not } r(a) \wedge \text{not } r(b)$  is eliminated if there is also the stronger fact  $p(a) \leftarrow \text{not } r(b)$ .
- Since the first conditional fact is implied by the second, this does not change the models.

## Duplicate Elimination (2)

### Algorithm (Elimination of Non-Minimal CFs):

Let a cond. fact  $C$  with  $m$  literals be generated.  
Get new comparison number  $N$  (inc. counter);  
**for each** literal  $L$  in  $C$  **do**  
    **for each** existing CF  $C'$  that contains  $L$  **do**  
        **if**  $C'.\text{ComparNo} \neq N$  **then**  
             $C'.\text{Overlap} := 1$ ;  $C'.\text{ComparNo} := N$ ;  
        **else** increment  $C'.\text{Overlap}$ ;  
        **if**  $C'.\text{Overlap} = C'.\text{length}$  **then**  
             $C$  is redundant  
        **else if**  $C'.\text{Overlap} = m$  **then**  
             $C'$  is redundant

## Duplicate Elimination (3)

- **Seminaive evaluation:** At least one body literal must be matched with a new conditional fact (derived in the previous iteration).
- **Possible Improvements (not yet implemented):**
  - ◇ It is possible to make the resolvable literal in a disjunctive fact unique (reduces the number of ways to derive the same disjunction).
  - ◇ It is possible to determine an evaluation sequence for the rules and iterate only selected rules.

# Residual Program (1)

- **Positive Reduction:** If  $q$  appears in no head, then **not**  $q$  is obviously true, and e.g.

$$p \leftarrow \mathbf{not} q \wedge \mathbf{not} r$$

can be strengthened to  $p \leftarrow \mathbf{not} r$ .

- **Negative Reduction:** If there is an unconditional fact  $q \vee r$ , then **not**  $q$  and **not**  $r$  cannot both be true, and e.g.

$$p \leftarrow \mathbf{not} q \wedge \mathbf{not} r \wedge \mathbf{not} s$$

can be deleted.

## Residual Program (2)

- The residual program is constructed from the hyper-resolution fixpoint by evaluating default negation in obvious cases, i.e. applying positive and negative reduction (and elimination of non-minimal CFs).
- It is equivalent to the original program under e.g. the static and the stable model semantics.
- Positive reduction can be efficiently implemented with an counter for occurrences in the head and a linked list to occurrences in the body, negative reduction uses the above overlap technique.

# Overview

1. Computation of Residual Program

2. Static Semantics

3. Query Evaluation

4. Stable Models

## Note

- The current algorithm is quite inefficient, but
  - ◇ As far as I know, SLP is still the only implementation of the static semantics.

A direct application of the definition of the static semantics is impossible. But further improvements of the algorithm are possible.
  - ◇ The static semantics is a very well-behaved generalization of the WFS to disjunctive programs.
  - ◇ Normally, very few negations remain in the residual program. The computation can be restricted to these “critical negations”.

# Static Model Computation (1)

- Static interpretations for the critical negations are computed as follows:
  - ◇ At first, all possible interpretations for the critical negations are tried.
  - ◇ For each such interpretation, the conditions of the conditional facts are evaluated, and minimal models of the remaining disjunctions are computed (only for ground literals that appear in negations).

## Static Model Computation (2)

- An interpretation  $I$  of the default negations is only possible if there is a set of minimal models  $J_1, \dots, J_n$  such that for all atoms  $p$ ,  $I \models \mathbf{not} p$  iff  $J_1 \models \neg p$  and  $\dots$  and  $J_n \models \neg p$  (and if  $I$  can be extended to a model).
- This condition can be checked without trying all subsets of the current set of minimal models:
  - ◇ One selects all models  $J_i$  that make no  $p$  true for which  $\mathbf{not} p$  is true in  $I$ .
  - ◇ Then one only has to check that for each  $\mathbf{not} p$  that is false in  $I$ , there is  $J_i$  with  $J_i \models p$ .

# Static Model Computation (3)

- This condition restricts the possible interpretations for the default negation literals.
- But then the set of minimal models is reduced.
- And so on, until a fixpoint is reached.

## Possible Improvement (not yet implemented):

- It is possible to avoid considering all possible interpretations for the default negation atoms at the beginning (one can start directly to construct minimal models).

# Example (1)

- Consider the following program:

$$p \vee q \leftarrow \text{not } r.$$
$$q \leftarrow \text{not } q.$$
$$r \leftarrow q.$$

- Let the query be **not**  $p$ .

- The residual program is:

$$p \vee q \leftarrow \text{not } r.$$
$$q \leftarrow \text{not } q.$$
$$r \leftarrow \text{not } q.$$
$$r \vee p \leftarrow \text{not } r.$$
$$\text{\$answer} \leftarrow \text{not } p.$$

## Example (2)

- Residual program (again):

$$p \vee q \leftarrow \text{not } r.$$

$$q \leftarrow \text{not } q.$$

$$r \leftarrow \text{not } q.$$

$$r \vee p \leftarrow \text{not } r.$$

$$\text{\$answer} \leftarrow \text{not } p.$$

- If **not**  $q$  and **not**  $r$  are both false,  $p$ ,  $q$  and  $r$  must be false in a minimal model.
- If **not**  $q$  is true,  $q$  and  $r$  must be true, and  $p$  false.
- And so on.

## Example (3)

- Minimal models

(reduced to ground atoms appearing in negations):

No	$p$	$q$	$r$
1	false	false	false
2	true	false	false
3	false	true	true

- Still possible interpretations for default negations:

No	<b>not</b> $p$	<b>not</b> $q$	<b>not</b> $r$
1	true	true	true
2	false	true	true
3	true	false	false
4	false	false	false

## Example (4)

- This reduces the set of minimal models (minimal model 2 is based on the interpretation that makes **not**  $r$  true and **not**  $q$  false: no longer possible).

No	$p$	$q$	$r$
1	false	false	false
3	false	true	true

- Remaining interpretations for the default atoms:

No	<b>not</b> $p$	<b>not</b> $q$	<b>not</b> $r$
1	true	true	true
3	true	false	false

## Example (5)

- This means that **not**  $p$  is true in all static models.

$$\text{\$answer} \leftarrow \text{not } p.$$

- D-WFS (Brass/Dix) and the well-founded circumscriptive semantics (You/Yuan) do not imply **not**  $p$  in this example.

$$p \vee q \leftarrow \text{not } r.$$

$$q \leftarrow \text{not } q.$$

$$r \leftarrow q.$$

- Under the static semantics the given rule  $r \leftarrow q$  implies **not**  $r \rightarrow \text{not } q$ .

# Overview

1. Computation of Residual Program
2. Static Semantics
3. Minimal Model Computation
4. Query Evaluation
5. Stable Models

# Minimal Model Generator (1)

- Input is a set  $\mathcal{D}$  of minimal positive disjunctions.
- For each ground atom  $p$  that should be assigned a truth value (appears in critical negation):
  - ◇ If  $p$  does not appear in  $\mathcal{D}$ :  $p$  is false.
  - ◇ If  $p$  appears as a fact in  $\mathcal{D}$ :  $p$  is true.
  - ◇ If  $p$  appears in  $n$  proper disjunctions,  
 $n + 1$  cases are considered (with backtracking):  
 $p$  is false or  
 $p$  is true required by one of the  $n$  disjunctions.

## Minimal Model Generator (2)

- If e.g. the disjunction  $p \vee q \vee r$  was selected to explain that  $p$  must be true, the ground atoms  $q$  and  $r$  are made false.
- Assumed truth values are used to update the disjunctions:
  - ◇ True ground atoms are asserted as disjunction, which eliminates all disjunctions that contain the ground atom (they are non-minimal).
  - ◇ False ground atoms are removed from the disjunctions (which makes them stronger).

# Minimal Model Generator (3)

## Positive Aspects of the Algorithm:

- Never runs into dead ends.
- No additional minimality test required.
- Can generate partial minimal models.
- Space complexity polynomial in the size of the input disjunctions.

## Negative Aspects:

- The same model may be generated more than once.

# Overview

1. Computation of Residual Program
2. Static Semantics
3. Minimal Model Computation
4. Query Evaluation
5. Stable Models

# Query Evaluation (1)

- A query  $\psi$  with answer variables  $X_1, \dots, X_n$  is added to the program as the formula

$$\text{\$answer}(X_1, \dots, X_n) \leftarrow \psi.$$

- All derived conditional facts that directly or indirectly used this rule contain  $\text{\$answer}$  in the head.
- Since the rule does not really belong to the program, these conditional facts must be ignored when
  - ◇ doing positive reduction and when
  - ◇ computing minimal models of the program.

## Query Evaluation (2)

- Disjunctive answers are computed from conditional facts in the residual program that contain only **\$answer**-literals in the head:
  - ◇ One simply checks whether the condition is true in all static interpretations.
  - ◇ In many cases, default negation was already evaluated by positive and negative reduction, so no condition remains in the residual program.

# Overview

1. Computation of Residual Program
2. Static Semantics
3. Minimal Model Computation
4. Query Evaluation
5. Stable Models

# Stable Models (1)

- **Theorem:** The transformation into the residual program does not change the set of stable models.
- **Theorem:** Let  $P$  be a disjunctive program without positive body literals. A Herbrand interpretation  $I$  is a stable model of  $P$  iff it is a model of Clark's completion  $\text{comp}(P)$ .

- Clark's completion of a disjunctive program: Treat

$$p \vee q \leftarrow \mathbf{not} r \quad \text{like} \quad \begin{array}{l} p \leftarrow \mathbf{not} q \wedge \mathbf{not} r. \\ q \leftarrow \mathbf{not} p \wedge \mathbf{not} r. \end{array}$$

## Stable Models (2)

- SLP constructs Clark's completion as
  - ◇ a set of pure positive disjunctions (the rules),
  - ◇ and a set of pure negative disjunctions (the completion axioms).

Only ground atoms are considered that still appear in the residual program (all other ground atoms are certainly false).

- E.g.  $p \leftarrow \mathbf{not} q, q \leftarrow \mathbf{not} p$  has the completion  $p \vee q, \neg p \vee \neg q$ .
- Duplicate and non-minimal disjunctions are eliminated as before.

# Stable Models (3)

## Model Generation:

- If a positive or negative disjunction consists only of one element, the corresponding truth value is immediately assigned to the ground atom.
- Then the model generator loops over all ground atoms that still appear in the residual program.
- If an atom is not yet assigned a truth value, the model generator considers both possibilities (with backtracking).

## Stable Models (4)

- Assigned truth values are used to update the disjunctions:
  - ◇ The current assumption is added as one-element disjunction. Eliminates non-minimal disjunctions.
  - ◇ The complement of the assumption is removed from the disjunctions (they become stronger).
- This might make the truth value of other ground atoms obvious. If an atom is assigned both true and false, an inconsistency is detected.

# Conclusion

- SLP is the first implementation of the static semantics and one implementation of disjunctive stable models (with constraints).
- I plan to continue the work on SLP (HTTP server, more semantics, completion of documentation).
- For simple examples, the efficiency is more than sufficient.
- There are ideas for improving the efficiency, but that would require some motivation (e.g. users).
